Satellite images show link between wood pellet demand and increased hardwood forest harvesting.

SOUTHERN ENVIRONMENTAL LAW CENTER

A new satellite image analysis, conducted by researchers at Clark University, shows a strong link between wood pellet demand from Enviva's mills in North Carolina and Virginia and hardwood forest harvesting in the area. Specifically, the analysis concludes that the area's ecologically valuable hardwood forests have been harvested at a higher rate since Enviva's pellet mills started operating and consuming primarily hardwoods and that nearly half of this wood is going to Enviva's Ahoskie, Northampton, and Southampton mills, likely contributing to overall declines in carbon stocks in the area's hardwood forests. Additionally, this analysis found—in direct contradiction to repeated industry claims—that from 2001-2016 forest harvesting in Enviva's sourcing area exceeds growth, resulting in a net loss of forested area. Moreover, in the time period after Enviva's three mills started operating (2011-2016), the area's hardwood forests experienced a net loss. Taken together, this analysis (as well as years of photographic evidence) contradicts or otherwise highlights the misleading nature of many of the industry's main arguments. Instead of enhancing forest carbon and decreasing emissions, policies that subsidize large-scale burning of forest biomass undermine global efforts at addressing climate change. Now, at a time when urgent climate action is needed, governments must move away from forest biomass and invest instead in genuine climate solutions.

Introduction

We are in the midst of a global climate and biodiversity crisis, with scientists warning that we must take critical action now if we hope to minimize some of the worst impacts, such as extreme heat, drought, catastrophic flood, and unprecedented species extinction.[1] Protecting intact forests is of utmost importance to addressing this dual threat, and yet the biomass industry is using trees harvested from the Southeast's natural forests to manufacture wood pellets for use as fuel in power stations. These pellets are overwhelmingly shipped overseas to be burned for electricity as an alternative to coal. However, just like burning fossil fuels, burning forest biomass increases carbon dioxide pollution in the atmosphere, and this increase can persist for several decades or more—far outside of relevant timeframes for climate action.

Wood pellets are made mostly from living trees,[2] which are taken to pellet mills, ground into chips, dried, and formed into pellets. Enviva, the world's largest wood pellet manufacturer, currently operates nine pellet mills throughout the southeast—three of which source wood from forests primarily within the coastal plain area of northeast North Carolina ("NC") and southeast Virginia ("VA").

A new report by researchers at Clark University,[i] commissioned by the Southern Environmental Law Center ("SELC"), takes a closer look at the impacts of wood pellet harvesting on the forests around three of Enviva's wood pellet mills—which are located in Ahoskie, NC; Northampton, NC; and Southampton, VA (the "three-mill area"). Researchers analyzed satellite images of forests in the sourcing areas of these mills to evaluate forest loss (i.e., harvesting or clearing) over time and by forest type.

The report concludes that:

- **Hardwood forest harvesting increased in the three-mill area after Enviva's pellet mills started operating, returning to and then exceeding pre-2008-2010 recession harvest levels.**
- **From 2011-2016, hardwood forest harvests exceeded growth, resulting in a net loss of hardwood forest cover in the area around Enviva's pellet mills.**
- **From 2016-2018, Enviva's three mills consumed nearly half of all wood from hardwood forest clearings in the three-mill sourcing area.**
- **Sourcing for Enviva's mills is likely contributing to overall declines in carbon stocks in hardwood forests in the three-mill area.**

When discussing impacts to forests, the industry typically prefers to focus on national or regional trends in forest growth, rather than localized impacts in the sourcing area associated with specific pellet mills. This analysis exposes how such an approach skews conclusions about the industry's impacts on forests and therefore masks its footprint. While Enviva tries to downplay the impact of the pellet industry by stating that wood pellets account for less than 3% of total wood harvesting in the southeast,[3] this analysis shows that when evaluating the actual forests being harvested for biomass, the impact is much larger: Enviva consumed close to half of all wood from hardwood harvesting in the sourcing area around its three pellet mills. Moreover, Enviva often proclaims the climate benefits of its practices by relying in part on the fact that forest growth in the southeast exceeds harvests.[4] Once again this analysis shows this to be misleading—in fact, harvests exceed growth in the actual sourcing area of Enviva's pellet mills.

At a time when we must urgently act to stabilize our climate and protect nature, we must invest in genuinely low-carbon energy sources and protect our natural forests as vital carbon sinks. The results of this analysis add to a large body of research showing that the forest biomass industry is not a climate solution and threatens both goals by driving additional harvesting of natural forests. This further calls into question policies in the European Union and United Kingdom that continue to support and heavily subsidize burning of forest biomass in power stations. It should also give pause to any country, including the United States, that is considering including largescale burning of forest biomass in its energy plans.

Background

Over the last decade, wood pellet manufacturing in the southeast U.S. has exploded—increasing fivefold from 2012 levels. Most of these pellets are being produced for export overseas, primarily to Europe, where they are burned for energy production under the guise of being clean and climate beneficial. In reality, an established body of scientific research shows that burning forest biomass for electricity increases carbon pollution in the atmosphere for decades or more, exacerbating climate change.[5] In particular, the use of whole hardwood trees taken from clearcut forests has been shown to be the most carbon-intensive form of biomass, increasing

[i] The full report is available at https://selc.link/3Bm7bKf.

carbon pollution for nearly a century.[6] Biomass sourced in this way routinely enters energy supply chains in the U.K. and other top biomass-importing countries in Europe.[7]

Despite the detrimental effects of the industry on the climate, the woody biomass industry is supported by billions of dollars annually in E.U. and U.K. subsidies that are aimed at addressing climate change. Biomass energy producers are able to receive these subsidies if they can demonstrate on paper that the wood pellets they are burning meet specified "sustainability criteria." However, these criteria do not address lifecycle carbon emissions and most importantly fail to account for the CO_2 emissions from burning the pellets.[8] As a result, the industry receives massive subsidies despite increasing carbon in the atmosphere.[9]

Enviva Pellets

Enviva, a primary supplier to Drax's U.K. power plant,[10] has been operating pellet mills in the Southeast U.S. for over ten years. Its flagship facility in Ahoskie, NC began manufacturing wood pellets in 2011, and was followed shortly thereafter by Enviva's Northampton, NC (early 2013) and Southampton, VA (late 2013) mills. As originally constructed, these three pellet mills had a combined production capacity of 1.4 million metric tons per year, but now have an annual production capacity of over 1.9 million metric tons after receiving permits authorizing expansions at two mills. In 2016, Enviva started operating its Sampson, NC mill and then a mill in Hamlet, NC in 2019.

Since 2013, multiple independent, on-the-ground investigations have uncovered destructive sourcing practices used to supply wood to Enviva's NC and VA mills.[11] These investigations found that Enviva's mills routinely source whole trees and other large-diameter wood (rather than claimed "residues" or "wastes"), and that many of these trees are taken from clearcuts of ecologically valuable and highly biodiverse natural upland and lowland hardwood forests, including bottomland hardwood and other wetland forests. These forests, located in the North American Coastal Plain global biodiversity hotspot, are some of North America's most valuable ecosystems; they provide key habitat to many at-risk species, including migratory songbirds, purify the air and improve water quality, and store large amounts of carbon.

Despite this and other evidence, Enviva continues to argue that its practices are not harmful to forests or the climate. The company even suggests that demand for wood pellets is actually benefiting forests by providing a market to keep and grow forests. Specifically, Enviva has repeatedly argued that it is not "driving harvests"[12] and that "forest inventories have increased" since Enviva began operating.[13] However, evidence on the ground suggests that these claims may be untrue in certain sourcing areas. To date, however, there has not been a large-scale quantitative measurement of the impacts of wood pellet demand on the pattern and rate of forest clearings by forest type and whether forest harvesting has increased in pellet mill sourcing areas. Researchers at Clark University undertook to answer these questions through an analysis of satellite images, the results of which were compiled into a final report: *Forest Clearing Rates in the Sourcing Region for Enviva Pellet Mills in Virginia and North Carolina, U.S.A.*

Satellite Image Analysis

Methodology: The report utilized best-available satellite data to map the harvesting of forests in the sourcing region for Enviva's three pellet mills in northeastern NC and southeastern VA. First, Clark University researchers analyzed harvesting over key time periods to detect whether harvesting has increased concurrent with mill operations.[ii] Given that these three mills heavily rely on hardwood tree species,[iii] this analysis looked at harvesting rates by forest types to see if impacts of the pellet mills' operations are more strongly associated with certain types of forests in the area. To test the relationship between its findings and pellet mill *(continue on page 5)*

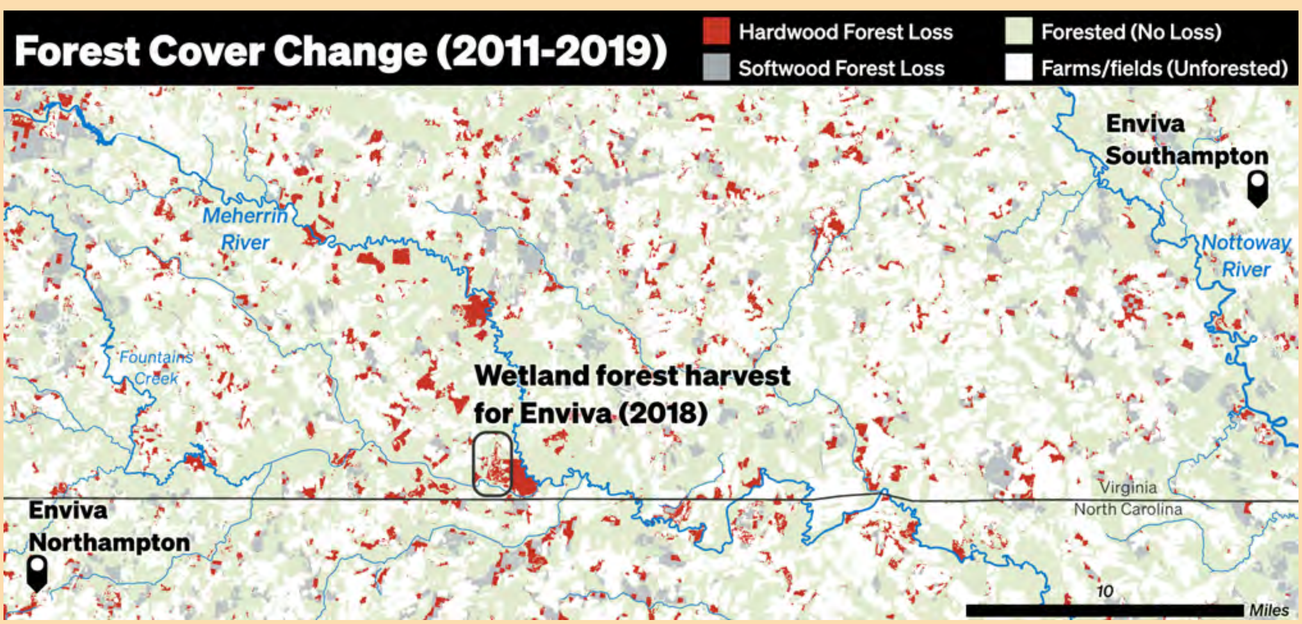
[ii] Clark University researchers used satellite data from Global Forest Watch and the National Land Cover Dataset. The analysis excluded forest disturbance and forest clearing events that are not likely to be related to market-driven biomass supply for wood products (e.g., developed areas, wildfires, and protected/non-harvestable land). For more information about the methodology, please see the full report.

[iii] The most recent Enviva-reported data shows the following hardwood percentages at these mills: Southampton (91%), Northampton (72%), and Ahoskie (63%). This information comes from Enviva's Supply Base Reports submitted to the Sustainable Biomass Program in 2020.

Satellite Images Confirm Investigation into Enviva's Use of Valuable Wetland Forests

In 2018, the U.K.'s Channel 4 "Dispatches" program conducted an independent investigation into Enviva's sourcing practices in NC and VA. This investigation identified an active clearcut of a mature wetland forest located less than half a mile from the Meherrin River in VA. Logging trucks carrying whole hardwood trees and other large-diameter wood were traced from this clearcut and documented entering Enviva's Southampton, VA pellet mill.*

Data from the satellite analysis confirmed that prior to the 2018 harvest this area was a forested wetland, comprised primarily of oak/gum/cypress tree species. Moreover, as shown below, this harvest site is located in an area along the NC and VA border that has experienced significant loss of hardwood forest cover from 2011-2019, according to the satellite image analysis.



* Anthony Barnett, *Dispatches: The True Cost of Green Energy*, Channel 4 (aired Apr. 16, 2018), https://ecostorm.tv/2018/04/16/the-real-cost-of-green-energy-dispatches/; *see also* note 7.

demand, the researchers utilized a time-series analysis—looking at both a pre-pellet mill and pre-recession time period (2004-2008) and a post-pellet mill period (2013-2018).[iv] Second, as part of a separate analysis, the researchers analyzed annual harvesting and growth rates from 2001 to 2016 in order to assess the potential net forest loss in the area over time. Finally, as part of both of these analyses, the researchers also looked at forest cover data around Enviva's Sampson, NC mill (the "Sampson area"), which commenced operations in the southeastern portion of the state in 2016.

Hardwood Harvesting & Pellet Demand: The analysis found an increase in forest harvesting in both the three-mill sourcing area and the Sampson area after Enviva's respective pellet mills started operating, showing a clear connection between demand for wood for the pellet mills and forest harvesting.

The rate of harvesting[v] of the area's hardwood (i.e., deciduous) forests were the most telling results of this analysis. Enviva's own self reporting demonstrates that its Ahoskie, Northampton, and Southampton mills rely predominately on hardwoods, and the satellite imagery analysis confirmed that the rate of hardwood forest harvesting increased in the area around these mills after Enviva's pellet mills started operating.

As shown in the table below, although hardwood harvesting in the area was relatively high around 2004-2008, harvesting dropped during the recession and subsequent closure of the Franklin, VA hardwood pulp mill. This analysis shows that with Enviva's demand for wood, not only did the hardwood forest harvesting rate in the area return to pre-recession levels but it ultimately exceeded those levels by 2016 and through 2018. The report's authors thus concluded that, "[I]t is very likely that the initiation of the pellet mill operations contributed to elevated rates of deciduous forest clearing in the [three]-mill region beginning in the 2010s, and in the [Sampson] region beginning in 2016."[14]

Annual Hardwood Forest Harvesting Rates Over Time

	Forest Area in 2000	2004-2008 (Pre-Recession & Pre-Pellet)		2009-2012 (Recession)		2013-2018 (Post-Pellet)	
	[ac]	[ac/yr]	[%/yr]	[ac/yr]	[%/yr]	[ac/yr]	[%/yr]
Three-Mill	2,624,986	40,587	1.5%	30,075	1.1%	42,994	1.6%
Sampson	1,324,895	17,381	1.3%	16,316	1.2%	22,185	1.7%

Forest area in 2000 and the average annual rate of gross hardwood forest harvesting in select time periods for the three-mill and Sampson regions.

This same pattern held true in the Sampson sourcing area, reflecting the impacts on hardwood forests from Enviva's Sampson mill coming online in 2016. From 2004 to 2015, hardwood harvesting in this region ranged from 1.2% to 1.5% per year, but harvesting increased to 1.9% per year from 2016 to 2018 after Sampson started operating.

These findings, and the direct relationship between the increased harvesting levels and demand from Enviva's pellet mills, are further supported by the U.S. Forest Service's Timber Products Output ("TPO") data.[15] As shown in Figure 1, harvesting for bioenergy/fuelwood in the three-mill area increased from just over 500,000 green tons in 2011 to 4.8 million green tons in 2019.[16] Similarly, harvesting for bioenergy/fuelwood in the Sampson region increased from 155,000 green tons in 2011 to 1.8 million green tons in 2019, with a marked increase after the Sampson mill started operating.[vi]

[iv] Although this first analysis was focused on forest loss in the three-mill area, as noted, researchers at Clark University wanted to be able to also assess the impact of the Sampson mill's more recent activity. To do so, they separated the post-pellet time period into two ranges, with 2013-2015 representing the time immediately after the three mills started operating and 2016-2018 representing the time after all of the mills, including Sampson, were online.
[v] The forest harvesting rate is calculated by dividing the area of forest cleared in a given year by the area of forest in 2000, the baseline for the analysis.
[vi] Review of the TPO data was separate from the analysis conducted by Clark University researchers.

U.S. Forest Service Data Reveals Enviva's Reliance on Sawtimber Trees—Not Low Value or Waste Materials

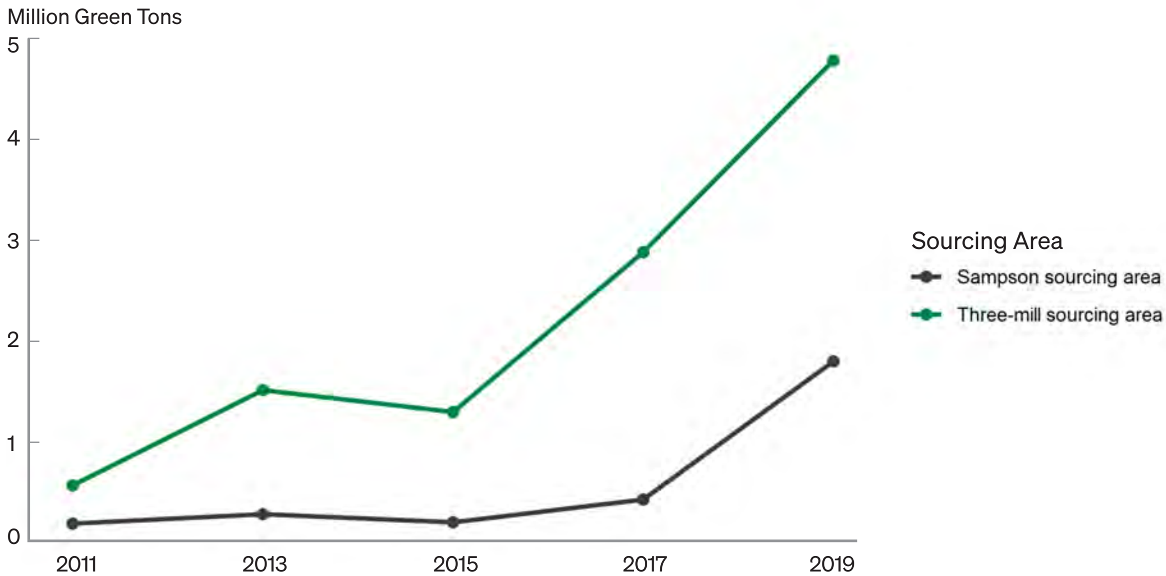
As part of the U.S. Forest Service's Forest Inventory and Analysis ("FIA") program, the Service compiles the TPO dataset. SELC's geospatial analysts reviewed the TPO data from 2001 to 2019 for the counties in NC and VA that fall within the three-mill and Sampson sourcing areas identified by researchers at Clark University. To assess the impact of Enviva's pellet mills, this analysis focused on the TPO removal or harvest category called "bioenergy/fuelwood," which includes all harvesting to manufacture wood pellets as well as other fuelwood uses such as industrial boiler fuels at mills. Based on Enviva's self-reported data regarding its feedstock use at the relevant pellet mills, wood pellet production appears to be the single largest use of wood harvested as "bioenergy/fuelwood."

Review of this TPO data reinforces the findings of the satellite image analysis and further underscores what on-the-ground investigations have shown for years—Enviva's pellet mills in northeastern NC and southeastern VA rely heavily on larger-diameter hardwood trees—and directly contradicts Enviva's repeated claims that its pellet mills use wastes, residues, and low-value roundwood.

FIGURE 1

Forest Harvesting for Bioenergy/Fuelwood

Wood pellet sourcing areas, 2011-2019



Moreover, a closer look at hardwood harvesting for bioenergy/fuelwood in the three-mill sourcing area shows that the overwhelming majority (approx. 84%) of hardwood material comes from larger diameter whole trees that could otherwise be used for sawtimber.* Given the share of this material going to Enviva's Ahoskie, Northampton, and Southampton mills, this data slams the door firmly shut on Enviva's claims that its pellet mills rely predominately on wastes, residues, and low-value roundwood that has no other use.

The U.S. Forest Service categorizes the hardwood material harvested as either "non-growing stock," which includes tops, limbs, stumps, and crooked or rotten "cull" trees (what Enviva refers to as "low value") or "growing stock," which is the main bole of the tree. The growing stock is then divided into two categories depending on the size of the tree, with the larger diameter trees categorized as "sawtimber growing stock" and the smaller diameter trees categorized as "poletimber growing stock." As shown in Figure 2, only a small fraction

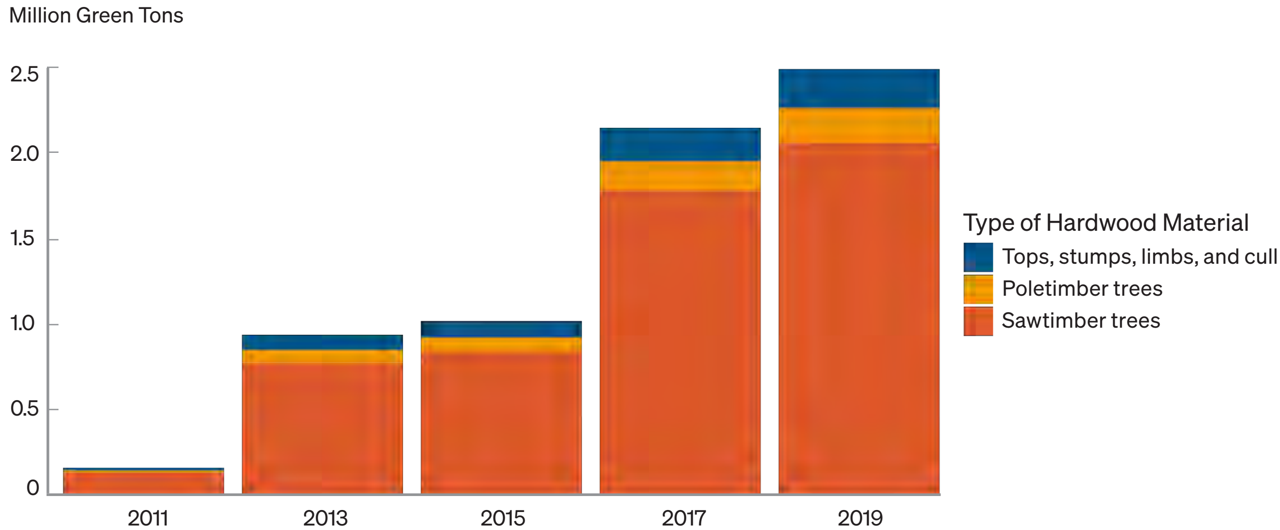
* The Service defines sawtimber trees as live trees with a diameter outside bark (d.o.b.) of at least 11 inches for hardwood and 9 inches diameter at breast height (d.b.h.) for softwood. These are larger than poletimber trees. U.S. Forest Service, *Forest Inventory & Analysis Glossary*, https://www.nrs.fs.fed.us/fia/data-tools/state-reports/glossary/.

of the hardwood material harvested for bioenergy/fuelwood comes from the non-growing stock category. Instead, this material is almost exclusively from trees classified as sawtimber.

FIGURE 2

Type of Hardwood Material Harvested for Bioenergy/Fuelwood

Three-mill sourcing area, 2011-2019



Net Forest Loss

The first part of the satellite analysis, discussed above, looked at the gross rates of forest clearings to assess whether and to what extent demand for wood for Enviva's pellet mills has impacted forest harvesting rates in the region. Separately, the Clark University researchers also assessed the average net value of forested area within the three-mill region through 2016.[vii] This distinct analysis compared annual rates of forest harvesting with gains to determine whether the area's forests have experienced a net loss over time.

The analysis found that from 2001-2016, the amount of forests being harvested exceeded any new growth in the three-mill region, resulting in a net loss of forested area. Specifically, the forested area decreased annually by 4,467 acres during this time period (for a loss of 1.18%), with losses concentrated in the area's deciduous, mixed, and woody wetland forests. Similarly, a net loss of forested area was also shown in the Sampson sourcing area over this same time period. Moreover, in the years following Enviva's operation of the Ahoskie, Northampton, and Southampton mills (from 2011-2016), hardwood forests in the area around the mills also experienced a net loss. In that six-year period, the area's deciduous, mixed, and woody wetland forests decreased by almost 28,000 acres (4,638 acres/year).[viii] Loss to the area's natural hardwood forests is particularly concerning—biodiversity at the landscape scale, in form of diverse forest types, provides important ecosystem services, including habitat for a rich variety of wildlife, resistance against pests and climate stressors, water and nutrient cycling, and beyond.

Based on these findings, and in direct contrast to Enviva's repeated assertions, the report's authors conclude that, "pellet mill operations do not appear to have induced an increase in forestland area within the [three-mill] region, and in fact deciduous forestland saw a sizeable and steady decline."[17]

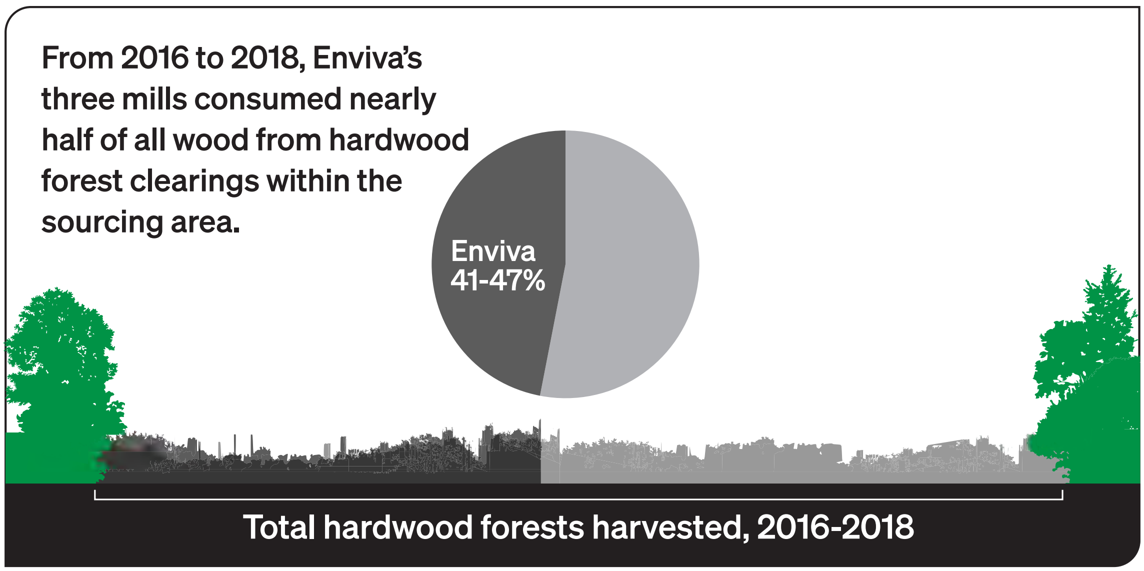
[vii] Satellite images related to forest gains were only available through 2016.

[viii] A small net gain in the area's softwood forests during this time resulted in a minimal overall increase in forested area in the area from 2011-2016 (approx. 0.14%), although as noted above the area's hardwood forests experienced a net loss.

Enviva's Consumption

In addition to analyzing the amount of hardwood forest harvesting occurring in the three-mill region, the report was also able to conclude that from 2016 to 2018 Enviva's Ahoskie, Northampton, and Southampton mills consumed between 41% and 47% of all woody materials from hardwood forest harvesting within the three-mill area.

This conclusion is based on Enviva's own self-reported data regarding the sourcing practices of these three mills, including the amount of materials consumed by these mills during the relevant time period (between 2.33 and 2.66 million green tonnes per year), the percentage of this material that came directly from the forests (87%), and the percentage of this material that came from hardwood species (78%).[18] Using all of this data, the report's authors estimate that approximately 68% of Enviva's feedstock would have come to the mills directly from recent hardwood harvests in the area. Comparing that to the results of the satellite analysis, they conclude that, "pellet mill operations consume a correspondingly large fraction of the total deciduous forest clearing within the [three-mill] region."[19]



Forest Carbon Stocks

Finally, although a detailed assessment of forest carbon stocks was not a part of this analysis, with the information obtained during the study regarding forest harvesting rates, declining hardwood forest cover, and the percentage of hardwood harvesting going to Enviva, the report's authors were able to conclude that, "it is likely that Enviva sourcing is contributing to overall declining carbon stocks in deciduous forests in the [three]-mill area."[20] This conclusion is further supported by recent research by the Woodwell Climate Research Center and Chatham House, which countered industry claims that biomass demand incentivizes landowners to keep or even expand their forests, stating:

"These claims are based on economic theory and are not consistent with the empirical evidence, which suggests the opposite. Demand for wood for energy leads to a reduction in the forest carbon stored because the total area and volume harvested increases to meet this demand."[21]

Enviva itself has acknowledged that in situations such as these, the use of wood pellet biomass is not beneficial to the climate: "If growth and sequestration are not keeping up with harvest, then we agree that the emissions from biomass combustion should not be treated as climate friendly."[22]

Conclusion

While Enviva and others in the industry like to point out that wood pellet harvesting only accounts for a small percentage of overall harvesting in the Southeast, such a region-wide approach masks the impacts this industry is having on our natural forests. When researchers zoomed in to examine the forests directly harvested for these pellet mills, as in the satellite image analysis, the results show a strong link between the operation of Enviva's Northampton, Ahoskie, and Southampton mills and increased rates of hardwood forest harvesting in the area. The analysis also found that "a correspondingly large fraction" (41-47%) of all hardwood material being cleared in the area was being consumed by Enviva for use in pellet manufacturing and that over time the area's forests, including its ecologically valuable hardwood forests, have experienced a net loss in forest cover.

Urgent climate action is needed now. This must include a drastic reduction in emissions, as well as significant increases in forest carbon sinks. Indeed, all the pathways identified by the IPCC to address the climate crisis in its 2018 special report on keeping global warming below 1.5°C involve both. The forest biomass industry sets back efforts on both sides of this equation, increasing carbon dioxide in the atmosphere as pellets are burned in power stations to produce electricity and contributing to overall declining carbon stocks in the forests supplying trees for the production of wood pellets. To address the climate emergency, subsidies for the large-scale use of forest-biomass for energy must be ended and countries like the U.S. must avoid putting in place similar policies or incentives for this false solution, favoring instead genuine solutions like wind, solar, and battery storage.

Definitions

Total Hydrocarbons	All organic compounds containing hydrogen and carbon that are detected by a flame ionization detector operated in accordance with U.S. EPA Method 25A.
Volatile Organic Compounds	All organic compounds that are emitted to the atmosphere in a gaseous or vapor form that can participate in photochemical reactions to produce ozone. All volatile organic compounds are considered VOCs unless specifically exempted in 40 CFR 51.100(s). Relevant excluded compounds include methane, ethane, and acetone.
VOC Emissions	Mass emissions of VOC measured on a pounds of carbon basis.

Acronyms

DHM	Dry Hammermill
EPA	U.S. Environmental Protection Agency
FID	Flame Ionization Detector
FTIR	Fourier Transform Infrared Spectrometer
GHM	Green Hammermill
HAP	Hazardous Air Pollutant
MC	Moisture Content
MDEQ	Mississippi Department of Environmental Quality
ODT	Oven Dried Tons
THC	Total Hydrocarbons
VOC	Volatile Organic Compounds
C1	Carbon

Units of Measure

ppm	Parts per million (wet basis)
ppmvd	Parts per million (dry basis)
ppm C_3	Parts per million as propane
ppm C_1	Parts per million as carbon
mg	Milligram
kg	Kilogram
µg	Micrograms

Permit Designations/Titles

Green Hammermill	AA-001, Wet Wood Hammermill
Dryer	AA-002, Wood-Fired Rotary Dryer
Dry Hammermill	AA-003, Dry Wood Hammermill
Aspiration System	AA-004, Pellet Cooler Process and AA-005 Pellet Mill Aspiration System

Air Emission Test Report
Amory, Mississippi Wood Pellet Production Facility

1. SUMMARY

Enviva Pellets, Amory, LLC (Enviva) has sponsored air emission testing to satisfy the requirements of Agreed Order 6267-13 dated June 16, 2013 (the "Order"). These test results are being submitted to the Mississippi Department of Environmental Quality (MDEQ) by October 31, 2013 in accordance with the Order.

The scope of the testing program included volatile organic compounds (VOCs) and six organic hazardous air pollutants (HAPs). Annual emissions of each analyte have been calculated and compared to applicable permit limits. The results of the testing program are summarized in Table 1-1 based on the present maximum permitted production limit of 99,000 output tons per year in the permit.

Table 1-1. Total Emissions at Plant Permit Limit 0f 99,000 Tons/Year (dryer outlet) for the Dryer and Green Hammermill and 8,760 hours for the Dry Hammermill and Aspirator

Analyte	Dryer	Dry Hammermill	Green Hammermill	Aspirator	Total
Total VOC	29.9	41.72	12.71	100.89	185.3
Methanol	2.50	0.34	1.37	0.73	4.94
Acetaldehyde	0.00	0.00	0.00	0.00	0.00
Acrolein	0.00	0.00	0.00	0.00	0.00
Formaldehyde	0.64	0.00	0.00	0.00	0.64
Phenol	0.00	0.00	0.00	0.00	0.00
Propionaldehyde	0.00	0.00	0.00	0.00	0.00
Total HAPS	3.14	0.34	1.37	0.73	5.58

At the current maximum permitted production limit, VOC emissions are above the facility wide limit of 99.0 tons per year but are below the PSD threshold of 250 tons per year. The total HAP emissions are under 25 tons per year, and each of the HAPs has an emission rate less than 10 tons per year.

The air emission tests were conducted by Air Control Techniques, P.C. using EPA Reference Methods 1, 2, 3, 4, 25A, and 320 in accordance with the test protocol submitted to MDEQ on July 31, 2013[1]. The emission tests were conducted from Monday, October 14 through Wednesday, October 16, 2013. This report summarizes the emissions test data, quality assurance data, test method procedures, sampling equipment calibrations, process operating conditions, and test program participants.

2. EMISSION TEST PROGRAM DESCRIPTION

2.1 Amory, Mississippi Plant Description

Enviva operates a plant producing wood pellets. The plant consists of a wood receiving yard, log debarkers and chippers, a rotary dryer, a hammermill, and an aspiration system serving the pellet presses and coolers. The plant processes wood composed of a range of hardwoods and softwoods.

2.2 Purpose and Scope of the Emission Test Program

Based on a voluntary self-evaluation, Enviva reported to the Mississippi Department of Environmental Quality (MDEQ) that it may have underreported emissions of volatile organic compounds (VOCs) in its permit application. Enviva's concern was based on a set of engineering-oriented tests [2] conducted in November 2012 that indicated that VOC emissions from a hammermill source and a press cooler aspiration vent may be higher than previously known. While emissions from specific wood pellet plants are highly dependent on the specific equipment employed and, to a lesser degree, the hardwood/softwood mix of raw material, Enviva's preliminary findings in the November 2012 engineering test are generally consistent with other recent findings in the Wood Pellet Industry, specifically the engineering-oriented tests[3] at a Georgia Biomass, Inc. plant in Waycross, Georgia and Green Circle Bio Energy in Cottondale, Florida.

This air emission testing program is intended to address Enviva's concern and fulfills the requirements of the Order. Specifically, Enviva agreed to generate VOC emissions data for the following sources.

- Dryer stack
- Dry Hammermill stack
- Green Hammermill stack
- Pellet Mill and Cooler Aspiration System

2.3 Test Participants

The Enviva project manager for this project was Mr. Michael Doniger, Director of Plant Operations. He was assisted by Mr. Joe Harrell, Environmental Manager, Mr. Mike Jones, and Mr. John Burns, Amory Plant Manager.

Mr. Michael J. Doniger, Director, Plant Operations

Enviva retained Air Control Techniques, P.C. to conduct the air emission testing program at the Amory plant. The Air Control Techniques, P.C. project manager was John Richards, Ph.D., P.E, QSTI. He was assisted by David Goshaw, P.E., QSTI, Todd Brozell, P.E., QSTI, and Jonas Gilbert. Tom Holder, QSTI provided quality assurance services for the test program. Contact information for Air Control Techniques, P.C. includes the following.

Air Control Techniques, P.C.
301 East Durham Road
Durham, N.C. 27513
Phone: (919) 460-7811

3. TEST MATRIX AND TEST RESULTS

3.1 Test Matrix

Table 3-1 summarizes the test program analytes, sampling methods, and analytical methods used for the four sources listed in Section 1.1.

Table 3-1. Test Matrix, Air Emission Testing
Enviva Pellets, Amory, Mississippi

Analyte	Test Method	Number of Runs	Run Length	Analytical Method
Acetaldehyde, Acrolein, Formaldehyde, Methanol, Phenol, Propionaldehyde	EPA Method 320	3	60 min	FTIR
Gas Flow	EPA Method 2	3	60 min	Manometer
Gas Molecular Weight, Oxygen, Carbon Dioxide	EPA Method 3	3	60 min	Fyrite® Analyzer
Gas Moisture	EPA Method 4	3	60 min	Gravimetric
Total Hydrocarbons (THC)	EPA Method 25A	3	60 min	FID

The tests were conducted on Monday, October 14 through Wednesday October 16, 2013.

3.2 Test Results

The VOC and organic HAP test results and calculated annual emission rates are summarized in Tables 3-2 through 3-5. VOC and HAP emissions were measured simultaneously at each of the four emission units tested.

The VOC emissions have been calculated based on the total hydrocarbon data provided by Method 25A. The Method 25A data have been converted from a wet to a dry basis to account for the moisture in the stack gas stream. Total hydrocarbon concentrations (THC) have been used as a surrogate for VOCs.

The VOC emission calculations do not include any corrections for methane, ethane, or acetone despite the fact that these compounds are detected by Method 25A but are not classified as VOCs. Accordingly, the reported VOC emissions are biased to higher-than-true levels to the extent that these three compounds affected the Method 25A results.

The Method 25A data reflect the combined THC concentrations consisting of (1) alpha and beta pinene, (2) numerous other terpenes such as limonene and 3-carene, and (3) the organic HAPs. The organic HAP emissions discussed later in this report are also classified as VOCs and represent a small fraction of the total VOC emissions reported.

Method 320 was used to measure six organic compounds. Several of the organic compounds were below the detection limits of Method 320 in this matrix of gaseous constituents. These non-detection concentrations are designated by shading in Tables 3-2 through 3-5.

1. Note: Shaded area indicates a calculated minimum detection limit. Emissions were calculated based on zero for non-detect values.

Four test runs were conducted on the dry hammermill. During the first run conducted on October 15, 2013, problems relating to either stones entering the hammermill or problems with the hammers were causing the system to malfunction. The unit was inspected overnight and found in good condition. Three additional runs were conducted on October 16, 2013. All four runs were included in the test averages.

Phenol, lbs/ODT	0.000	0.000	0.000	0.000	0.000
Propionaldehyde, lbs/ODT	0.000	0.000	0.000	0.000	0.000

1. Note: Shaded area indicates a calculated minimum detection limit. Emissions were calculated based on zero for non-detect values.

3.3 Emissions Data Evaluation

Method 25A VOC Concentrations

The VOC emissions from the various process units ranged from 0.03 to 1.6 pounds per ODT. VOC emissions expressed on a pounds per ODT basis were highest from the aspiration system.

The data summarized in Tables 3-2 through 3-5 indicate that the total VOC emissions from the Amory Plant exceed 100 tons per year calculated as carbon. These tests confirm that the plant is a Title V major source for VOCs.

The accuracy of the VOC data is demonstrated by a Method 25A response factor of approximately 1 for the group of compounds present in the gas stream. The Method 25A response is expressed in terms of a response factor that is defined as the observed Method 25A concentration divided by the true concentration. The Method 25A FID has a response factor close to 1.0 for a large set of organic compounds. Some high molecular weight organics have a response factor larger than 1, and in some cases, approaching 1.5. For these compounds, Method 25A is biased to higher-than-true concentrations. Some low molecular weight-highly oxygenated organic compounds such as methanol and formaldehyde have very low response factors in the range of 0.1 to 0.4. For these compounds, Method 25A is biased to lower-than-true concentrations.

As part of the laboratory tests reported to MDEQ in Enviva's Phase I emission study dated July 31, 2013[4] (the "Phase I Study"), Air Control Techniques, P.C. has taken the following two independent approaches in assessing the Method 25A response factors: (1) direct measurement of the Method 25A response factor using an alpha-pinene gas standard, the dominant organic compound measured during the laboratory tests and (2) a comparison of the Method 25A concentration data with the summed concentrations of all of the specific organics measured simultaneously using NCASI Method 98.01 and EPA Method 18. The results of these response factor analyses are presented in Tables 3-6 and 3-7.

Table 3-6. Alpha-Pinene Method 25A Response Factor[1]	
Alpha-Pinene Gas Standard, as $C_{10}H_{16}$	259 ppm
Alpha-Pinene Gas Standard, as C_3	863 ppm
FID Response, as C_3	888 ppm
Response Factor as C_3	1.03

1. Note: This table was included in the Phase I Study report to MDEQ.

Table 3-7. Calculated Method 25A Response Factors in Phase I Laboratory Tests[1]					
Run	Process Type	Softwood Content, %	Method 25A versus Combined NCASI 98.01 and Method 18	Dominant Compounds	Other Important Compounds
4	Dryer	10	0.72	α-and β-Pinene	Acetone, Methanol
5	Dryer	10	0.70	α-and β-Pinene	Acetone, Methanol
6	Dryer	10	0.75	α-and β-Pinene	Methanol, Formaldehyde
21	Dryer	10	1.23	α-and β-Pinene	Acetone, Methanol
22	Press	10	1.05	α-and β-Pinene	Acetone, Methanol
7	Dryer	70	0.85	α-and β-Pinene	Acetone
8	Dryer	70	0.90	α-and β-Pinene	Acetone
9	Dryer	70	1.02	α-and β-Pinene	Acetone
10	Dryer	70	0.91	α-and β-Pinene	Acetone
24	Press	70	1.51	α-and β-Pinene	Acetone, Methanol
11	Dryer	100	0.99	α-and β-Pinene	Acetone
12	Dryer	100	0.96	α-and β-Pinene	Acetone
13	Dryer	100	0.85	α-and β-Pinene	Acetone
14	Dryer	100	0.87	α-and β-Pinene	Acetone
16	Dryer	100	1.09	α-and β-Pinene	Methanol, Acetone
19	Dryer	100	1.21	α-and β-Pinene	Methanol, Acetone
20	Press	100	1.13	α-and β-Pinene	Methanol, Acetone
Test Program Average			0.98		

1. Note: This table was included in the Phase I Study report to MDEQ.

The excellent agreement between the Method 25A total concentration and the combined concentrations of all of the organics measured by NCASI 98.01 and EPA Method 18 demonstrate that Method 25A is an appropriate VOC measurement technique for wood pellet production facilities.

Method 320 HAP Concentrations

At the maximum permitted production limit of 99,000 ODT per year for the dryer/GHM, and maximum potential operations of 8,760 hours for the DHM/aspiration sources, all six of the organic HAPs are each emitted at less than 10 tons per year. The total HAP emissions for the plant are less than 25 tons per year.

The list of HAPs specifically included in the test protocol included methanol, acetaldehyde, acrolein, formaldehyde, phenol, and propionaldehyde. This list was compiled based on (1) the organic compounds identified in laboratory analyses of pellet production facilities emissions, (2) previous emission tests conducted in the Pellet Manufacturing Industry, and (3) organic HAPs identified in studies of other wood products industries—specifically, MDF production.

The results of this test program indicate that this list of HAPs compounds needs to be amended. Phenol was not detected in any of the tests of the four process units. Propionaldehyde was also not detected in any of the tests.

The non-detectable phenol emissions data are consistent with the results of the Phase I Study. Phenol was not identified at detectable concentrations in any of the laboratory studies summarized in the Phase I Study report. The emission rates of phenol reported in a November 2012 Wiggins report [2] ranged from 0.0002 to 0.0018 pounds per hour—all insignificant emission rates. Phenol was also not listed in previous emission tests reviewed in preparation for this test program. Phenol was included in the test protocol primarily because other researchers such as Beauchemin and Tampier,[5] Milot, [6] and Milot and Mosher [7] listed phenol due to its inclusion in tests conducted at MDF and particleboard facilities. However, phenol emissions in MDF and particleboard production are due to the use of phenolic resins and similar binders. There is no reason to expect any appreciable phenol formation in pellet production considering (1) the lack of binders of any type in pellet production, (2) the higher moisture levels in pellet production as compared to MDF and particleboard processes, and (3) the lower material temperatures in pellet process equipment. Air Control Techniques, P.C. has assigned zero values to non-detected concentrations.

Acetaldehyde, propionaldehyde, and acrolein had very low concentrations in most of the emission tests summarized in this report. The IR absorption spectra of both water and the terpene compounds overlap the absorption spectra of acetaldehyde, propionaldehyde, and acrolein. Accordingly, the reported concentrations of these three compounds are biased to higher-than-true levels to the extent that this interference could not be avoided by Method 320 spectral absorption modeling. Zero values have been assigned when these concentrations were below detection limits of Method 320 due, in part, to the interference bias.

The use of zero values for non-detected compounds is an appropriate approach for any source, such as pellet production, where there are a few dominant compounds (i.e. methanol and formaldehyde) and a large number of possible compounds at extremely low levels such as phenol, acetaldehyde, and propionaldehyde. The use of non-detect or one-half non-detect concentrations in emission calculations for a large number of compounds potentially present at trace levels inherently makes any source “major” regardless of the actual emissions, size, or operations characteristics of the emission unit.

3.4 VOC and Organic HAP Emission Summary

Table 3-8 summaries annual emissions of VOC and organic HAP compounds. The annual emission rates are based on operation at the permit limited production rate of 99,000 ODT for the dryer/GHM, and maximum operations of 8,760 hours per year for the DHM/aspiration sources.

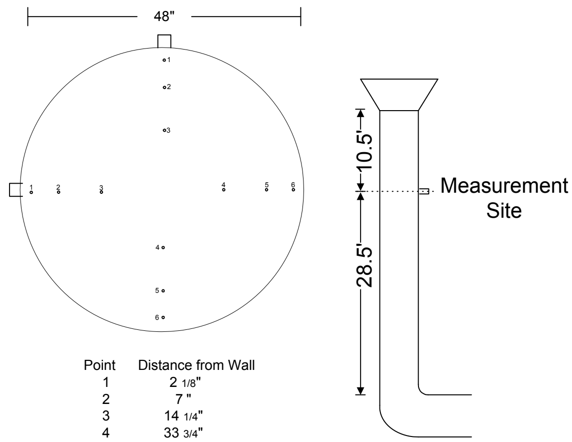
Table 3-8. Total Emissions at Plant Permit Limit 0f 99,000 Tons/Year for the Dryer and Green Hammermill and 8,760 hours for the Dry Hammermill and Aspirator

Analyte	Dryer	Dry Hammermill	Green Hammermill	Aspirator	Total
Total VOC	29.9	41.72	12.71	100.89	185.3
Methanol	2.50	0.34	1.37	0.73	4.94
Acetaldehyde	0.00	0.00	0.00	0.00	0.00
Acrolein	0.00	0.00	0.00	0.00	0.00
Formaldehyde	0.64	0.00	0.00	0.00	0.64
Phenol	0.00	0.00	0.00	0.00	0.00
Propionaldehyde	0.00	0.00	0.00	0.00	0.00
Total HAPS	3.14	0.34	1.37	0.73	5.58

4. SAMPLING LOCATIONS

4.1 Dryer Stack Sampling Location

The dryer sampling location meets EPA Method 1 location requirements as indicated in Figure 4-1. Twelve sampling points were used to measure the gas flow rate.



Point	Distance from Wall
1	2 1/8"
2	7 "
3	14 1/4"
4	33 3/4"
5	41 "
6	45 7/8"

Figure 4-1 Dryer # 1 Stack Sampling Location

The downstream[1] flow disturbance is the stack discharge. The upstream flow disturbance is the duct from the fan entering the base of the stack.

During the sampling program, only the port facing south was used. The port facing east was blocked by the stack support cable.

No cyclonic flow conditions were observed in the Dryer stack. The point-by-point cyclonic flow checks indicated an average flow angle 1.9 degrees. This meets the requirements of Section 11.4 of Method 1. A photograph of the Dryer stack is shown in Figure 4-2.

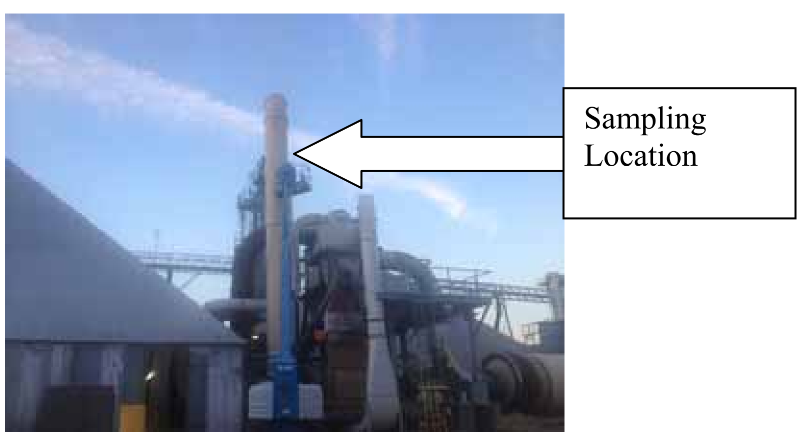


Figure 4-2. Photograph of the Dryer Stack

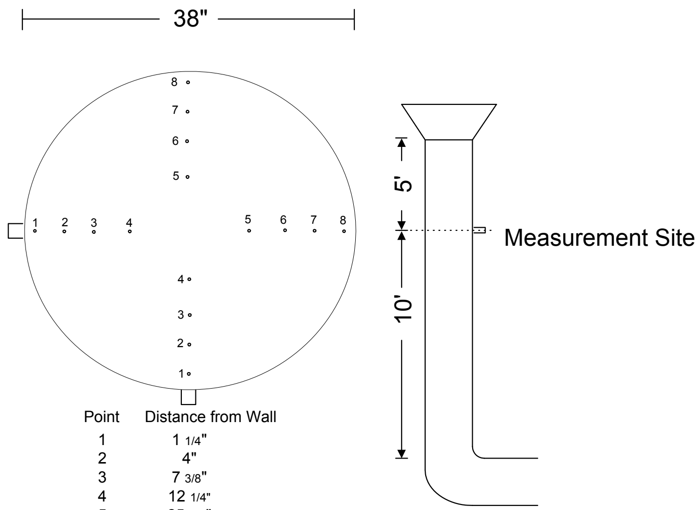
[1] "Upstream" and "downstream" are defined based on the sampling location as the reference point.

4.2 Dry Hammermill Stack Sampling Location

The Dry Hammermill sampling location meets EPA Method 1 location requirements as indicated in Figure 4-3. Twelve sampling points were used to measure the gas flow rate.



Point	Distance from Wall
1	1 1/4"
2	4"
3	7 3/8"
4	12 1/4"
5	25 3/4"

7	34"
8	36 3/4"

Figure 4-3. Dry Hammermill Sampling Location

The downstream flow disturbance is the stack discharge. The upstream flow disturbance is the fan discharge duct. During the sampling program, both ports were accessible.

No cyclonic flow conditions were observed in the Dry Hammermill stack. The point-by-point cyclonic flow checks indicated an average flow angle of 1.9 degrees. This meets the requirements of Section 11.4 of Method 1. A photograph of the Dry Hammermill stack is shown in Figure 4-4.

Figure 4-4. Photograph of the Dry Hammermill Sampling Location

4.3 Pellet Mill Aspiration System Sampling Location

The Aspiration System sampling location meets EPA Method 1 location requirements as indicated in Figure 4-5. Twelve sampling points were used to measure the gas flow rate.

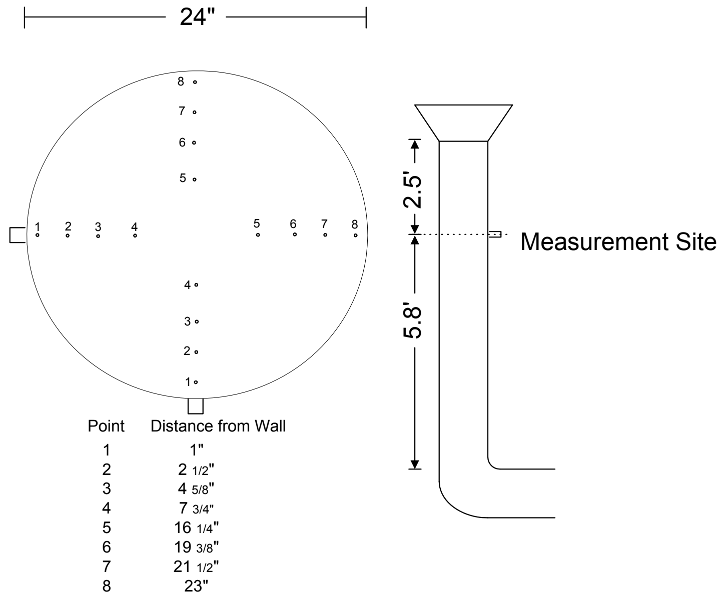

Figure 4-5. Pellet Mill Aspiration System Sampling Location

The upstream flow disturbance was an entry duct to the fan inlet. The downstream flow disturbance was an elbow from the multicyclone collector.

No cyclonic flow conditions were observed in the Aspiration System outlet duct. The point-by-point cyclonic flow checks indicated an average flow angle of 3.1degrees. This meets the requirements of Section 11.4 of Method 1. A photograph of the Aspiration System sampling location is shown in Figure 4-6.

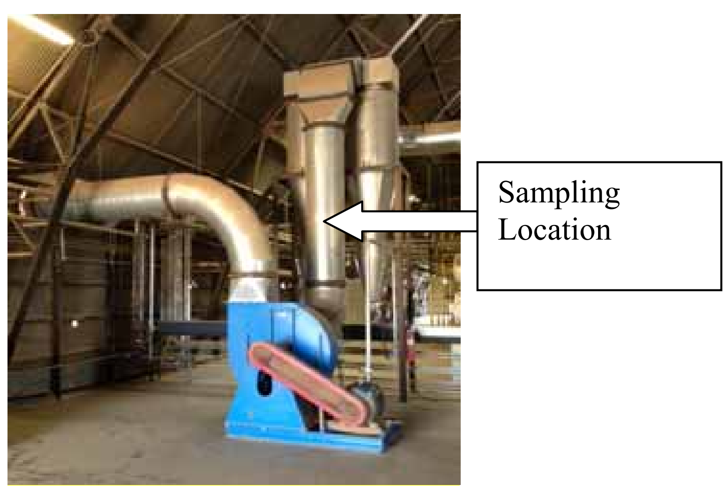

Figure 4-6. Photograph of the Pellet Mill Aspiration System Sampling Location

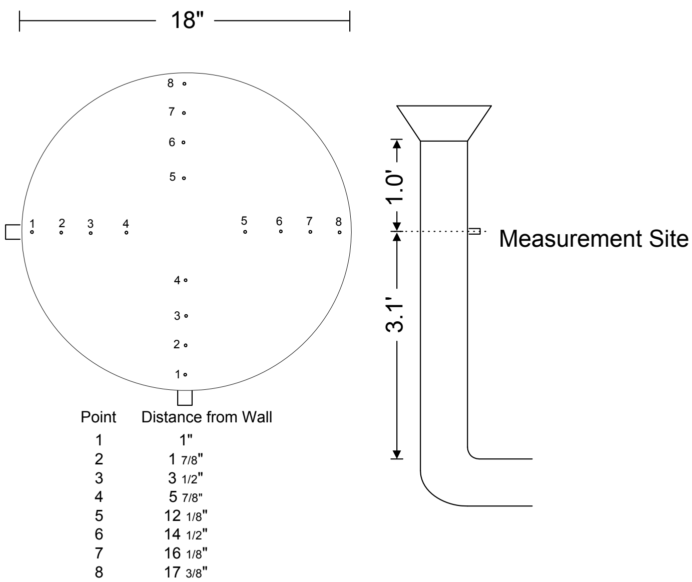
4.4 Green Hammermill Stack Sampling Location

The Green Hammermill stack sampling location shown in Figure 4-7 meets the minimum requirements for a downstream flow disturbance specified in Method 1, Section 11.1. The downstream flow disturbance is the fan discharge duct. The upstream flow disturbance is the stack discharge. Both ports were accessible for sampling.



Point	Distance from Wall

6	14 1/2"
7	16 1/8"
8	17 3/8"

Figure 4-7. Green Hammermill Stack Sampling Location

No cyclonic flow conditions were observed in the Green Hammermill stack. The point-by-point cyclonic flow checks indicated an average flow angle of 2.6 degrees. This meets the requirements of Section 11.4 of Method 1. A photograph of the Green Hammermill stack is shown in Figure 4-8.

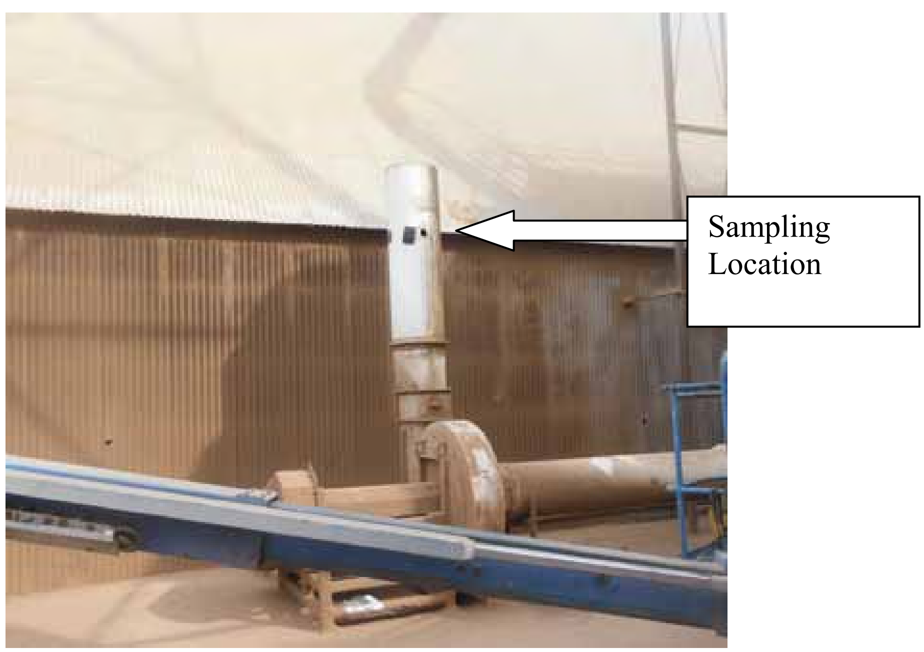

Figure 4-8. Green Hammermill Stack

5. TESTING PROCEDURES

5.1 Flue Gas Velocity and Volumetric Flow Rate - EPA Method 2

The flue gas velocities and volumetric flow rates during all of the emission tests were determined according to the procedures outlined in U.S. EPA Reference Method 2. Velocity measurements were made using S-Type Pitot tubes conforming to the geometric specifications outlined in Method 2. Accordingly, each Pitot was assigned a coefficient of 0.84. Velocity pressures were measured with fluid manometers. Effluent gas temperatures were measured with chromel-alumel thermocouples attached to digital readouts.

5.2 Flue Gas Composition and Molecular Weight - EPA Method 3

Flue gas analyses and calculation of flue gas dry molecular weights were performed in accordance with EPA Method 3. A stainless steel probe was inserted into the gas stream to collect a representative sample of the flue gas during each test run. The samples were analyzed using a Fyrite gas analyzer. Moisture was removed from the sample gas by means of a knockout jar located prior to the sample pump.

5.3 Flue Gas Moisture Content - EPA Method 4

The flue gas moisture content was determined in conjunction with each test run according to the sampling and analytical procedures outlined in EPA Method 4. Wet impinger sampling trains were used to withdraw and analyze the stack gas. The impingers were connected in series and contained water in the first two impingers followed by an empty impinger and then a silica gel impinger. The impingers were contained in an ice bath to assure condensation of the flue gas stream moisture. Any moisture that was not condensed in the impingers was captured in the silica gel; therefore, all moisture was weighed and entered into moisture content calculations.

5.4 Total Hydrocarbons – EPA Method 25A

Continuous emissions monitoring was conducted for volatile organic compounds. The sampling and analytical procedures for VOCs were conducted in accordance with EPA 25A. The CEM system consisted of a sample acquisition system, the THC emission monitor, and a data acquisition system (DAS). A California Analytical Model 300 flame ionization detector was used for the Method 25A tests.

The sample acquisition system included an in-stack probe, a heated out-of-stack glass mat filter for particulate matter removal, a heat-traced Teflon® sample line, a Teflon® heated-head pump, a moisture removal system, and a gas manifold board. All components of the sample acquisition system that contacted the sampled gas were constructed of Type 316 stainless steel or Teflon®. The sample gas was continuously extracted from a central point within the duct at a constant rate (±10%) for the duration of each test run. The wet, filtered gas was transported to a heated-head pump located at the CEM laboratory. The sample gas was sent directly to the VOC analyzer. Care was taken to ensure that the sample gas was greater than 220°F during transport from the stack to the VOC monitor. All pretest and posttest calibration procedures were performed as outlined in the applicable EPA Reference Methods.

Total organic hydrocarbon concentrations were measured on a wet basis using a California Analytical 300 FID continuous emission monitor. The THC concentrations were monitored on a propane (C_3) basis using a flame ionization detector (FID). The FID was fueled by a gas mixture consisting of 40% helium and 60% hydrogen to reduce the effect of oxygen synergism. The THC analyzer was calibrated with a set of four gas standards. Calibration tests were performed prior to and following each test run.

Outputs from the individual emission monitors were connected to a computerized data acquisition system. Outputs from the analyzer were sent to a portable computer via a National Instruments™ FieldPoint controller. The signals were downloaded to a STRATA© software program every two seconds. The two-second readings were averaged for the duration of the test run.

Total mass emissions of VOCs were determined based on the Method 25A total hydrocarbon concentration data. The mass emissions were expressed on a pounds mass of carbon per hour.

5.5 Organic HAP Compounds – EPA Method 320

Testing for wet-basis organic HAP concentrations was conducted by extractive Fourier transform infrared (FTIR) spectroscopy using EPA Method 320 (40CFR, Part 63, Appendix A). Sample gas was continuously passed through the sampling system, which included an in-stack probe, a heated out-of-stack glass mat filter for particulate matter removal, a Teflon® heat-traced sample line, a MIDAC Fourier Transform Infrared (FTIR) spectrometer, a Teflon® heated-head pump, and a gas manifold board as shown in Figure 5-1. All components of the sample acquisition system that contacted the sampled gas were Type 316 stainless steel or Teflon®. All components of the sampling system and the FTIR cell were maintained at or above 120° C. Air Control Techniques, P.C. took great care to ensure that the sampling system contained no “cold spots” to prevent organic HAP loss. The sampling rate was maintained at greater than 10 liters per minute.

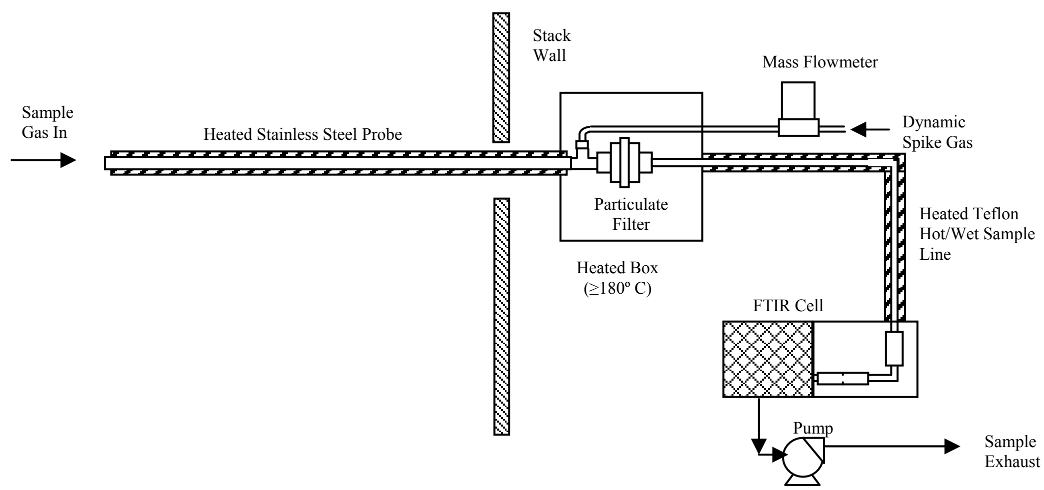

Figure 5-1. Method 320 Organic HAP Sampling System

The FTIR system included a MIDAC Corporation I-1301 spectrometer equipped with a heated, nominal 10-meter path absorption cell, a potassium bromide (KBr) beam splitter, zinc selenide (ZnSe) non-hygroscopic windows, and a liquid nitrogen-cooled Mercury Cadmium Telluride detector. Measurements were made using a MIDAC Model I-1301 high resolution Michelson interferometer with AutoQuant Pro software. Sample gas continuously passed through the sampling system, and sample spectra (based on 50 co-added interferograms) were recorded every minute. The system's nominal spectral resolution was 0.5 cm^{-1}. Samples and standards were analyzed at temperatures greater than 120°C and near ambient pressures.

The inside walls of the cells were polished stainless steel to minimize interaction of the sample with the cell walls, and the cell mirrors were of bare gold. The gas pressure in the FTIR sample cell was monitored with a pressure transducer connected directly to the sample cell. The heated sample cell was wrapped in an insulating thermal jacket, and the temperature was controlled with type J thermocouples. The absorption cell volume was approximately 2 liters.

The FTIR system was operated via a portable computer, and a data archive storage system (USB Mass Storage Drive) was used for data backup. All interferograms, single beams, absorbance spectra, and background single beams were stored and have been archived. The filename, time, pressure and temperature of the sample cell, scan rate, background identification and other pertinent information was recorded by hand during the test program.

Air Control Techniques used the program AutoquantPro™ Version 4.5.0.195, (©Midac Corporation, 2012) to collect and analyze all the infrared field data. The program allows the development and storage of analytical "methods" for analysis of spectral data (absorbance) files. The reference spectra used for these analyses were developed by MIDAC Corporation, EPA, and Enthalpy Analytical, Inc. One "model" was developed for determining the absorption path length and one additional "method" for determining the concentrations of the target compounds for each source.

The concentration uncertainty reported by AutoquantPro is called the Standard Error of the Estimated Concentration, or SEC; it is also known as the Marginal Standard Deviation. The uncertainties in the concentration are proportional to the square root of the sums of the squares of the residual. After the residual spectrum is obtained, which we will call R, the error variance for the case of a single reference spectrum is calculated as follows.

$$\sigma^2 = \frac{\sum_i R_i^2}{(n-1)}$$

Where n is the number of observations. The SEC is given by the following.

$$SEC = \frac{\sigma\, C}{\sqrt{\sum_i \mathrm{A}_i^2}}$$

Where **A** is the spectrum and **C** is the known concentration of the reference.

The 95% confidence interval is 1.96 times the SEC.

6. QUALITY ASSURANCE

6.1 Method 1 Quality Assurance

All S-type Pitot tubes used in this project conformed to EPA guidelines concerning construction and geometry. Pitot tubes were inspected prior to use. Information pertaining to S-type Pitot tubes is presented in detail in Section 3.1.1 of EPA Publication No. 600/4-77-027b. Only S-type Pitot tubes meeting the required EPA specifications were used in this project.

The thermocouples used in this project were calibrated using the procedures described in Section 3.4.2 of EPA Publication No. 600/4-77-027b. Each temperature sensor was calibrated at a minimum of three points over the anticipated range of use against NIST-traceable mercury in glass thermometer.

6.2 Method 4 Quality Assurance

Pretest and posttest leak checks were conducted on each Method 4 sampling train used. The observed leak rates for the sampling trains were below 0.02 actual cubic feet per minute as required by Method 4.

All dry gas meters were fully calibrated to determine the volume correction factor prior to field use. Post-tests calibration checks were performed as soon as possible after the equipment was returned to the laboratory. Pre-and post-test calibrations agreed within ±5 percent. The calibration procedure is documented in Section 3.3.2 of EPA Publication No. 600/4-77-237b.

The scales used at the test location to determine flue gas moisture content were calibrated using a standard set of weights.

6.3 Method 25A Quality Assurance

At the beginning of the test day, a linearity calibration test was performed on each analyzer. The continuous emission monitoring instrument response did not differ by more ±5 from the propane calibration standard. Linearity results for the test program are provided in Table 6-1 through 6-8.

Prior to and following each test run, a system calibration test was performed. The system test was performed to verify that the sampling system did not contain leaks (system bias) and to measure a change in analyzer response during the test program (system drift). The system bias was less than ±5% of full-scale, and system drift was less than ±3% of full scale. System calibration results for the test program are provided in Tables 6-1 through 6-8.

6.4 Method 320 Quality Assurance

Air Control Techniques, P.C. performed daily quality assurance checks. Background scans and calibration transfer standard (CTS) spectra tests were performed prior to and following each test series. An analyte spike was performed using methanol.

The flow rate at the outlet of the pump was measured while the probe was plugged to verify that the sampling system was leak free. The flow rate was less than 200 ml/min.

The FTIR cell was tested for leaks by closing the value while the cell was at minimum absolute pressure.

<u>Background Spectra</u>
Sample spectra were divided point-by-point by a 128-scan background recorded using N_2.
The single beam spectrum was constantly monitored, and a new background was generated following each test series or when residual and absorbance spectra indicated component build-up on the optical surfaces or alignment-related baseline shifts.

<u>Calibration Transfer Standards and Absorption Path Lengths</u>
A cylinder of 100 ppm ethylene in nitrogen served as the CTS. A CTS gas was introduced to the FTIR and allowed to reach steady state. The CTS was used to determine effective cell path length based on comparisons of the "field" CTS spectra to a laboratory CTS spectrum recorded by MIDAC. As shown in Table 6-6, the maximum path length deviation was less than 5% of the average.

Table 6-6. CTS Results Summary							
Date	Time	CTS Scan (pathlength)	SEC (ppm)	Cell Press. (psi)	Cell Temp (°C)	Deviation from Previous	Deviation from Average
14-Oct	1215	8.693	0.133	14.75	121	-0.2%	-0.2%

<u>Background Spectra</u>

On-site test personnel performed matrix spiking using a certified calibration standard of methanol and SF_6. The methanol gas standard was introduced into the sampling system upstream of the particulate matter filter at an average dilution ratio of less than 10% of the total sample volume. Analyte spiking was performed to demonstrate the suitability of the sampling system. The dilution factor was calculated based on the ratio of the SF_6 tracer gas analyzed directly by the FTIR and the in-stack measured concentration.

$$\frac{SF_6 \text{ during spike}}{SF_6 \text{ direct}} = DF$$

The recovery was calculated using the mean concentration of the spiked analyte (S_m), the native concentration of the analyte in the stack (S_u), the dilution factor (DF), and the cylinder concentration (C_s).

$$\text{Recovery}(\%) = \frac{\text{Sm} - \text{Su}\ (1 - \text{DF})}{\text{DFxCs}}$$

As shown in Table 6-7, the percent recovery was 100±30% as required by Method 320.

Table 6-7. Spike Recovery Results Summary						
Direct Cylinder Spike, ppm		System Spiked Gas, ppm		Native Concentration, ppm		Recovery, %
methanol	SF_6	methanol	SF_6	methanol	SF_6	
102.30	2.86	9.000	0.224	2.017	0.012769	94.5

Minimum Detectable Concentration
EPA Method 320 and the equivalent ASTM Standard D6348-03 specify a number of analytical uncertainty parameters that the analyst may calculate to characterize the FTIR system performance.

QA Review
Before the test program began, an analysis of possible analytical interferents (e.g., H_2O, CO_2, CO, pinenes) was conducted. Analytical wavelengths were determined to minimize analytical uncertainty and detection limits using reference spectra and the FTIR instrument that was used for the field testing.

At the conclusion of the testing, a quality assurance review of the test data was performed. This review included examination of the sample spectra and the quantitative analytical results. It also included spot-checking the analysis results by hand. These examinations included visual comparisons of the sample and reference spectra.

7. PROCESS DOCUMENTATION

Enviva Pellets Amory, LLC personnel logged the following process data during each test run of each process unit.

- Throughput in tons per hour (all process units)
- Inlet temperature (dryer)
- Outlet temperature (dryer)
- Cyclone static pressure drop (dryer, hammermill, presses)
- Wood feed % softwood content

Method 1 - Air Control Techniques, P.C.

Date: 10/14/2013

Client	Enviva
Job #	1909
Plant Name	Amory
State	Mississippi
City	Amory
Sampling Location	Dry Hammermill Baghouse

No. of Ports Available	2
No. of Ports Used	2
Port Inside Diameter, Inches	2
Distance From Far Wall To Outside Of Port, Inches	38
Nipple Length And/Or Wall Thickness, Inches	0
Depth Of Stack Or Duct, Inches	38
Stack Or Duct Width (if rectangular), Inches	
Equiv. Diameter = 2DW/(D+W), Inches	38
Stack/Duct Area, Square Feet	7.9
(□ x R^2 or L x W)	

	Upstream	Downstream
Distance to Flow Disturbances, Inches	120	60
Diameters	3.16	1.58

Note: If more than 8 and 2 diamteters and if duct dia. is less than 24" use 8 or 9 points.

Diameters			
Velocity	UP	Down	Particulate
12	8	2	12
12	7	1.75	12
12	6	1.5	16
16	5	1.25	20
16	2	0.5	24 or 25

Point Location Data

Point	% of Duct Depth	Distance From Inside Wall	Distance From Outside of Port
1	3.2	1 2/8	1 2/8
2	10.6	4	4
3	19.4	7 3/8	7 3/8
4	32.3	12 2/8	12 2/8
5	67.7	25 6/8	25 6/8
6	80.6	30 5/8	30 5/8
7	89.5	34	34
8	96.8	36 6/8	36 6/8

Method 1 - Air Control Techniques, P.C.

Date: 10/14/2013

Client	Enviva
Job #	1909
Plant Name	Amory
State	Mississippi
City	Amory
Sampling Location	Green Hammermill

Note: If more than 8 and 2 diamteters and if duct dia. is less than 24" use 8 or 9 points.

	Diameters		
Velocity	UP	Down	Particulate
12	8	2	12
12	7	1.75	12
12	6	1.5	16
16	5	1.25	20
16	2	0.5	24 or 25

No. of Ports Available	2	
No. of Ports Used	2	
Port Inside Diameter, Inches	2	
Distance From Far Wall To Outside Of Port, Inches	18	
Nipple Length And/Or Wall Thickness, Inches	0	
Depth Of Stack Or Duct, Inches	18	
Stack Or Duct Width (if rectangular), Inches		
Equiv. Diameter = 2DW/(D+W), Inches	18	
Stack/Duct Area, Square feet	1.8	
(□ x R^2 or L x W)		
	Upstream	Downstream
Distance to Flow Disturbances, inches	37.5	11.5
Diameters	2.08	0.64

Point Location Data

Point	% of Duct Depth	Distance From Inside Wall	Distance From Outside of Port	Too Close
1	3.2	5/8	5/8	1
2	10.6	1 7/8	1 7/8	
3	19.4	3 4/8	3 4/8	
4	32.3	5 7/8	5 7/8	
5	67.7	12 1/8	12 1/8	
6	80.6	14 4/8	14 4/8	
7	89.5	16 1/8	16 1/8	
8	96.8	17 3/8	17 3/8	17

APPENDIX E

Example Calculations

EXAMPLE CALCULATIONS

Run Number: Dryer – Run 1

Stack Gas Temperature, °R

$$T_s = 460 + ts$$

$$T_s = 460 + 199.6 = 659.6\ °R$$

Volume of Dry Gas Sampled at Standard Conditions, Dry Standard Cubic Feet

$$V_{mstd} = [17.64][\gamma][V_m]\left[\frac{\left(P_{bar} + \frac{\Delta H}{13.6}\right)}{T_m + 460}\right]$$

$$V_{mstd} = [17.64][0.9828][30.692]\left[\frac{\left(29.80 + \frac{1.00}{13.6}\right)}{543.8}\right]$$

$$V_{mstd} = 28.834\ ft^3$$

Volume of Water Sampled, SCF

$$V_{wstd} = 0.04715\ [\text{Weight of Condensed Moisture}]$$

$$V_{wstd} = 0.04715\ [83.8]$$

$$V_{wstd} = 3.951\ ft^3$$

Fraction of Water Vapor in Sample Gas Stream

$$\%H_2O = \left[\frac{V_{wstd}}{V_{mstd} + V_{wstd}}\right] \times 100$$

$$\%H_2O = \left[\frac{3.951}{28.834 + 3.951}\right] \times 100$$

$$\%H_2O = 12.05$$

Dry Mole Fraction of Flue Gas

M_{fd} = 1-%H2O/100

M_{fd} = 1-[12.05/100]

M_{fd} = 0.879

Molecular Weight of Sample Gas, Dry

$M_d = 0.44[\%CO_2]+0.32[\%O_2]+0.28[100-\%O_2-\%CO_2]$

$M_d = 0.44[2.0]+0.32[19.0]+0.28[100-19.0-2.0]$

M_d = 29.08 pounds/pound-mole

Molecular Weight of Sample Gas, Actual Conditions

$M_s = [M_d \text{ x } M_{fd}]+[0.18 \text{ x } \%H_2O]$

M_s = [29.08 x 0.879]+[0.18 x 12.05]

M_s = 27.74 pounds/pound-mole

Average Stack Gas Velocity, Feet/second

$$\text{vs} = K_p C_p \left(\sqrt{(\Delta p)}\right)_{avg} \left[\sqrt{\frac{T_s + 460}{P_s M_s}}\right]$$

$$\text{vs} = (85.49)(0.84)\left(\sqrt{(2.104)}\right)\left[\sqrt{\frac{659.6}{(29.61)(27.74)}}\right]$$

vs = 93.35 feet/second

Wet Volumetric Flue Gas Flow Rate at Stack Conditions, Cubic Feet per Minute

Q_{aw} = 60 x vs x A

Q_{aw} = 60 x 70.18 x 12.57

Q_{aw} = 70,382 Actual Cubic Feet per Minute

Dry Volumetric Flue Gas Flow Rate at Standard Conditions, Cubic Feet per Minute

$$Q_{sd} = 60 \times Mfd \times vs \times A \times \left[\frac{528}{ts + 460}\right]\left[\frac{Ps}{29.92}\right]$$

$$Q_{sd} = 60 \times 0.879 \times 93.35 \times 12.57 \left[\frac{528}{659.6}\right]\left[\frac{29.61}{29.92}\right]$$

Q_{sd} = 49,036 Dry Standard Cubic Feet per Minute

Average THC Dry Basis Concentration as Propane

C_{THCD} = (C_{THCW})/ (M_{fd})

Where: C_{THCd} = dry basis concentration of THC in ppm
M_{fd} = dry mole fraction from Method 4 concurrent run

C_{THCD} = 29.6 / 0.879 = 33.6 ppm THC as propane

Average THC Dry Basis Concentration as Carbon

C_{THCD} = (C_{THCW}) x (3) / (M_{fd})

Where: C_{THCd} = dry basis concentration of THC in ppm
M_{fd} = dry mole fraction from Method 4 concurrent run

C_{THCD} = (29.6) x (3) / 0.879 = 100.8 ppm THC as Carbon

VOC Emission Rate in Pounds Per Hour

E_{VOC} = (C_{VOC}) (Q_{SD}) (60 min/hr) (C_F)

Where: Q_{SD} = measured flow rate in stack in dscfm
C_F = Conversion factor in lb/scf – ppm
C_F = 3.117×10^{-8} for Carbon

E_{VOC} = (100.8) (49,036) (60 min/hr) (3.117×10^{-8}) = 9.24 lb/hr as Carbon
